

Supply-Side Civic Engagement: How The Supply of Civic Opportunity Shapes Political Participation

Christian Hosam

Norris Davis

2026-08-20

Introduction

Few concepts within the study of politics hold as much purchase as the critical nature of civic life in shaping citizen's political engagement. When individuals are recruited, convened, and informed by civic organizations, participation is thought to follow. While this foundational truism is oft-repeated as a logical and necessary truth, historically it has been limited empirically by measures of the demand side of civic engagement: individual trust, networks, and dispositions, all of which have been in decline for some time [CITE]. Far less attention is placed on the *supply side* of civic opportunity; the civic infrastructure that may be available or present in a community, regardless of individual membership.

Generally, this demand side of civic engagement focuses on the effects of membership in civic associations has to an individual's propensity to be an active participant in democratic processes [CITE]. But to what extent do the meso-level features of civic organizations; the features that constitute the communities that they are embedded in, shape this propensity in ways that are distinct from individual-level membership?

Contemporary scholarship on civic associations, by focusing on the characteristics of those who join, necessarily dial in on the ways that this membership can predict other types of behavior. But as recent work by Stephanie Ternullo argues, "place politics - or the correlation between where people live and their partisanship - exists at multiple geographic scales." One way at getting at this, which is Ternullo's approach, is to compare similarly situated locations with differing partisan affiliations. Another approach, the one we take here, is to connect data on civic organizations aggregated to a local level with individual level survey data to track how the features of living within a community with a different composition of civic associations affects canonical measures of political participation, namely voter turnout and presidential vote choice.

To do this, we construct a dataset that merges data recently compiled by Martin de Vries, Hahrie Han, and Jae Yeon Kim that measures civic opportunity at the county level (Vries, Kim, and Han 2024) to

the 2024 wave of the Cooperative Post-Election Study (CMPS) (Frasure, Masuoka, and Ocampo n.d.) to more deeply understand what they call the supply-side of the component parts of developing social capital. We find that living in a county with a higher density of civic opportunities leads to a reduction in support for Donald Trump in the 2024 election. We also find that this same measure also predicts an increase in voter turnout, with a particularly strong impact for younger voters.

While previous literature has ably and thoughtfully explored the relationship between social capital and political engagement, we believe that we are the first to pair data on the universe of civic organizations with rich, fine-grained data on political behavior, giving us leverage to mine key insights into a question that is similar, yet distinct to what is currently asked in the literature. Rather than asking how civic organizations drive political participation, we ask how living in a place that is more concentrated with these organizations shape political behavior.

This contributes to the literature on social capital by articulating an alternative story that goes beyond the individual-level effects of civic bonds as driving these effects, instead focusing on ways that the formation of these bonds might be endogenous to the type of community in which they are forged. It contributes the literature on political behavior by exploring new tools to understand how local context shapes political decision-making in ways that are tied and untied from cognitive, psychologically-based models.

Why Study the Supply Side of Social Capital?

The features of a local community and their ability to shape a person's ability, desire, and choices of political participation are well-documented in the literature (Han 2014; Knack and Keefer 1997; Putnam 1995). There has been a recent suite of literature, however, that has raised questions about whether local features are being supplanted in importance by the importance of national-level trends. Work by scholars like Dan Hopkins which argue that much of the information that was previously gathered at the local level is now eaten up by heuristics about partisan cues that are largely generated through gathering information about federal-level elections (Hopkins 2018). However, this type of information is only one dimension and, as other literature suggests, sidesteps rather than disputes the argument of if and under what conditions local and residential context matters (Sharkey and Faber 2014). Part of the reason for this relative lack of scholarly attention is the lack of tools to do so. The demand side measures are largely drawn from self-reported survey measures that reflect individual's perception of their relationship to the state and their energy (or lack thereof) to participate in the democratic process. This is both substantively important and methodologically intuitive. Understanding the dynamics of local politics is thus important not only to evaluate demographic comparisons but also to understand what are the conditions under which people's decisions can be changed.

Another dimension of local politics that could very well matter are the composite features of a community that shape access, facilitate conversation and political awareness, and provide opportunities to take part in civic activities that could be understood by those who participate in them as important for reasons either partially relevant or fully orthogonal to those national trends. This therefore can be seen as a form of resistance to an approach in which presidential electioneering absorbs all political behavior,

particularly when it comes to the formation and maintenance of ideology (Cramer 2016; Rodden 2019). Further, given the federalist nature of the United States, there are also particular forms of economic dispossession that take place at the local level that can shape a variety of political outcomes and attitudes (Cummings and Boutcher 2009; Hankinson, Magazinnik, and Weissman 2024).

Put together, there is a need to connect the universe of civic associations and its distinct impacts on American politics with how these impacts are shaping political attitudes and, perhaps most importantly of all, if it drives political behavior.

To that end, recent work by Milan de Vries, Jae Yeon Kim, and Hahrie Han argues that without fine grained data on the resources available to different communities, we can know that social capital is a necessary precursor for social trust and cohesion but don't have anyway to know "without knowing where to go to cultivate it, or being able to ex ante anticipate where it might be strong or weak." (Vries, Kim, and Han 2024)

To get at this problem, the authors construct a dataset that takes a census of all civic organizations registered as non-profits with the IRS and pulls in information about the type of activities and opportunities for participation that they provide in order to track how civic opportunity is spread out across the country. And, in fact, they find that civic opportunity is itself correlated to many of the major forms of economic and political dispossession in the country. Their key variable of interest, civic opportunity (more on how they construct this measure below in the Methods section), is more concentrated in higher-income areas, areas with a higher proportion of non-Hispanic white residents, and a higher proportion of college graduates. Put another way, the chance to even take part in things that would serve as the pretext for forming civic bonds is itself tied to the ways that political opportunities are allocated.

But this leaves an open question on the table: to what extent does this inequality in civic opportunity shape political decisions for those people that are embedded within these locations? Is it the case that because civic opportunity and the density of that opportunity is tied to demographic and social factors that it is unhelpful in giving us insight, which ironically would undercut the need for such a measure to have been constructed? Or, alternatively, is it the case that by identifying the relationship between outcomes such as voting, we are able to assess the importance of civic opportunity in a stronger, more forceful way?

Our interpretation of the follow-up to de Vries, Kim, and Han is that they were using the measures that they constructed as outcome measures; dependent variables that they used to track the component features that predict living in a place that nurture or repel civic engagement. Our intervention is to instead use their measure as an input; an independent variable that we use to see how living in a place with more or less civic opportunities shapes political behavior, which we believe help pay off the promise of what they discuss in their article. What are the political manifestations of living in a place with a high concentration of organizations that give you the opportunity to develop your civic identity and practice? Does that opportunity translate into action?

Data Collection

To investigate the relationship between civic opportunity and political behavior, we merge the dataset constructed by de Vries, Kim, and Han (furthermore called the civic opportunity dataset) to the 2024 wave of the Collaborative Post-Election Study (CMPS) (Frasure, Masuoka, and Ocampo n.d.). We used the CMPS because it provided us with two critical advantages. First, it has an oversample of respondents from communities of color, allowing us a higher degree of leverage into the particularistic impact that race could have to the question at hand. In addition, each respondent also identified the county that they lived in, giving us the ability to merge to the civic opportunity dataset at the level of the county. Each row of our dataset thus includes all information from the CMPS wave at the respondent level along with all information for the composite opportunity measure constructed by de Vries et al at the county level.

For our purposes, civic opportunity refers to an index that each organization that the de Vries et al collected information on that includes whether that organization:

- provides volunteer opportunities,
- offers membership,
- offers ways to take civic or political action, or
- holds community events

They had an overall universe for their dataset of 564,559 organizations. They then constructed an index for civic opportunity by creating a dummy score for each of the four items, re-scaling it from 0 to 1 (1 being an organization doing all and 0 being it doing none), summing those scores and normalizing them, and categorizing them into equally sized quintiles to be able to differentiate between higher and lower civic density. We think this measure allows us to credibly quantify a distinct measure for the study of politics because it is substantively relevant to the study of civic engagement while also being parsimonious with respect to a consistent yet robust construction of factors that extant literature already says serves as an anchor for civic engagement and social cohesion.

We use this measure of what the authors call an opportunity score (but for the purposes of this paper will be called *civic density*) as an independent variable to ask questions that can guide a different, yet incredibly relevant set of questions about the aftermath of the 2024 presidential election. In this paper, we focus particularly on the question of the decision to vote or, more specifically, impact of civic density on voter turnout in the 2024 election.

Research Question

- *Did living in a county with a higher concentration of civic opportunity lead to higher voter turnout in the 2024 Election?*

Hypotheses

Given both the existing literature that

Limitations

A couple of limitations to our study that we'd like to flag: first, the de Vries et al dataset was constructed in 2020 while the responses were fielded and gathered in 2024. We could imagine that there was some level of attrition and addition to the universe of civic organizations in the intervening years. We are limited because the original authors only did that pull the one time so in replicating we can't be sure that the organizations are absolutely the most up-to-date. However, given that reporting on the establishment of non-profits suggest that it increases a net rate of 1.9-2% in a given year in addition to the fact that these organizations are inclusive of those organizations that would not provide any civic opportunities, we are confident that any results we find will nonetheless provide legitimate insight into our research questions.

Second, while we think that there are important insights to be drawn from understanding the type of organizations that are present within these measures, because its not present within the original dataset, we stick to just using the composite measure as our independent variable without any disaggregation under the hood in terms of if a county has a higher proportion of religious organizations, for example. However, we still feel like this composite measure, given the benefits that we outline above, is still insightful in its own right and testing its predictive power is a worthwhile endeavor to further our understanding of how civic engagement shapes American politics.

Finally, we also recognize that self-reported turnout and vote share could be prone to mis-identification by the respondent and that the growing gold standard for studies like this one are validated voter turnout data, such as the one collected by a firm such as Catalist. While we are heartened by the increased rigor that this brings, we believe that self-reported turnout is helpful on its own terms because while the outcome measures might be self-reported, the civic opportunity measure is not and given that what we're after is a better sense how individuals make sense of their political resources (Verba, Schlozman, and Brady 1995), we think of this as a benefit rather than a drawback for the purposes of this study.

Model

In order to get at the question of voter turnout, we estimate a model that regresses self-reported voter turnout on civic opportunity (denoted here as well as in de Vries et al as *opc*) along with a vector of relevant co-variates, including age, race, gender, education, income, and partisan identification.

$$VoterTurnout_i = \alpha_i + \beta(opc_i) + \Phi X_i + \varepsilon_i :$$

Does Civic Density Predict Turning Out to Vote?

Across a range of specifications, civic density clearly predicts an increase in voter turnout.
